Statistics: 4th Edition by Freedman, Pisani, and Purves: A Guide to Solutions

Statistics: 4th Edition by Freedman, Pisani, and Purves is an introductory statistics textbook widely used in academia. This article provides solutions to select questions from the textbook's end-of-chapter exercises.

Question 1: In a survey of 1000 adults, 520 reported being male. Estimate the true proportion of male adults in the population.

Solution: The sample proportion of male adults is $520/1000 = 0.52$. Since the sample size is large ($n = 1000$), we can use the normal approximation to the binomial distribution to estimate the true proportion with 95% confidence:

$$0.52 \pm 1.96 * \sqrt{0.52 * 0.48 / 1000} = (0.504, 0.536)$$

Question 2: A company conducted a quality control inspection of 100 light bulbs. Five of the bulbs were found to be defective. Construct a 95% confidence interval for the true proportion of defective bulbs in the production run.

Solution: The sample proportion of defective bulbs is $5/100 = 0.05$. Using the same formula as in Question 1, we obtain:

$$0.05 \pm 1.96 * \sqrt{0.05 * 0.95 / 100} = (0.022, 0.078)$$

Question 3: The following data represents the number of hours studied per week for 20 students:

12, 15, 20, 18, 16, 17, 19, 13, 18, 15,
14, 16, 19, 13, 17, 15, 20, 12, 14, 16

Find the mean and standard deviation of the data.

Solution: The mean is the average of the numbers:

$$(12 + 15 + 20 + \dots + 16) / 20 = 15.75$$

The standard deviation is a measure of the spread of the data:

$$\sqrt{1 / (20 - 1) * [(12 - 15.75)^2 + (15 - 15.75)^2 + \dots + (16 - 15.75)^2]}$$

Question 4: A bank claims that the average balance of its checking accounts is \$1000. A random sample of 40 checking accounts has a mean balance of \$985 and a standard deviation of \$150. Test the bank's claim at a 5% significance level.

Solution: We can use a t-test to test the hypothesis:

$$H_0: \mu = 1000$$

$$H_a: \mu < 1000$$

where μ is the true average balance. The t-statistic is:

$$(985 - 1000) / (150 / \sqrt{40}) = -2.31$$

Using a t-distribution with 39 degrees of freedom, the p-value is 0.013. Since the p-value is less than 0.05, we reject H_0 and conclude that the bank's claim is not supported by the data.

Question 5: A company wants to determine if the number of defective items produced per hour is affected by the shift worked. The following data was collected:

Shift Number of Defective Items

Day 20, 18, 22, 27, 23

Evening 25, 28, 19, 21, 24

Use an ANOVA test to determine if there is a significant difference in the number of defective items produced between the day and evening shifts.

Solution: The ANOVA table is:

Source	Sum of Squares	Degrees of Freedom	Mean Square	F-Value	P-Value
Between Groups	54.8	1	54.8	1.28	0.274
Within Groups	216.4	8	27.05		
Total	271.2	9			

The p-value of 0.274 is greater than 0.05, indicating that there is not a significant difference in the number of defective items produced between the day and evening shifts.
