What is the formula for the macro multiplier? The formula to determine the multiplier is $M = 1 / (1 - MPC)$. Once the multiplier is determined, the multiplier effect, or amount of money needed to be injected into an economy, can also be determined. This amount is calculated by dividing the total amount of spending needed by the multiplier.

What is the formula for the money multiplier? The formula for the money multiplier is simply $1/r$, where r = the reserve ratio. A little too easy, right? It's the reciprocal of the reserve ratio. When r is the reserve ratio for all banks in an

economy, then each dollar of reserves creates $1/r$ dollars of money in the money supply.

What is the formula for the tax multiplier? How is the tax multiplier calculated? The tax multiplier is calculated using a variable called MPC (marginal propensity to consume), which is the percentage of an increase in income that is spent. Tax multiplier is then calculated using the formula: $-MPC/(1-MPC)$.

Why is as upward sloping? The aggregate supply (AS) curve is the total quantity of final goods and services supplied at different price levels. It slopes upward because wages and other costs are sticky in the short run, so higher prices mean more profits (prices minus costs), which means a higher quantity supplied.

What is the formula for aggregate supply in macroeconomics? Short-run Aggregate Supply Equation The equation used to calculate the short-run aggregate supply is: $Y = Y^* + \alpha(P - P_e)$. In the equation, Y is the production of the economy, Y^* is the natural level of production, coefficient is always positive, P is the price level, and P_e is the expected price level.

Why is the LRAS vertical? The long-run aggregate supply curve is vertical because, in the long run, resource prices adjust to changes at the price level, which leaves no incentive for firms to change their output. In the long run, prices and wages have no effect on the aggregate supply curve.
