## **Solution Romer Advanced Macroeconomics 3rd**

**Question:** What is the Ramsey growth model?

**Answer:** The Ramsey growth model is a neoclassical economic growth model that predicts that optimal economic growth depends on the trade-off between present consumption and future investment. It shows that the optimal capital stock is determined by a balance between the desire for immediate consumption and the need for future growth.

**Question:** Explain the Solow growth model.

**Answer:** The Solow growth model is a simplified neoclassical growth model that focuses on exogenous technological progress. It predicts that the economy will eventually reach a steady state with constant capital and output per worker. Technological progress is the sole driver of long-run growth in this model.

**Question:** Describe endogenous growth models.

**Answer:** Endogenous growth models attempt to explain the sources of economic growth from within the model itself, rather than relying on exogenous factors like technological progress. They typically incorporate features such as human capital accumulation, innovation, and research and development.

**Question:** Discuss the role of government in economic growth.

**Answer:** The role of government in economic growth is complex and multifaceted. Governments can play a role in promoting growth through policies that encourage investment, innovation, and human capital development. However, excessive government intervention can also stifle growth by creating distortions and inefficiencies.

**Question:** What is the golden rule of capital accumulation?

**Answer:** The golden rule of capital accumulation is a result derived from the Ramsey growth model. It states that the optimal capital stock is that which maximizes steady-state consumption per person. This occurs when the marginal rate of substitution of consumption today for consumption tomorrow is equal to the real

interest rate.
