The Shapiro-Wilk and Related Tests for Normality

1. What is the Shapiro-Wilk test for normality? The Shapiro-Wilk test is a non-parametric statistical test used to assess whether a sample comes from a normally distributed population. It evaluates the degree to which the sample distribution differs from a normal distribution, with a W statistic ranging from 0 to 1. A lower W statistic indicates a greater deviation from normality.

2. How is the Shapiro-Wilk test performed? The Shapiro-Wilk test is typically performed using statistical software. The sample data is inputted, and the software calculates the W statistic based on the ordered sample values. The W statistic is then compared to a critical value from a distribution table to determine whether the sample significantly deviates from normality.

3. What are the advantages of the Shapiro-Wilk test? Compared to other normality tests, the Shapiro-Wilk test has several advantages:

- It is more powerful than other tests for small sample sizes ($n < 50$).
- It is sensitive to deviations from normality, including skewness, kurtosis, and multimodal distributions.
- It can handle missing values, as long as they are not systematic.

4. What are the related tests for normality? Besides the Shapiro-Wilk test, other related tests for normality include:

- Anderson-Darling test
- Jarque-Bera test
- Kolmogorov-Smirnov test
- Lilliefors test

5. When should the Shapiro-Wilk test be used? The Shapiro-Wilk test is commonly used in data analysis when it is essential to verify the normality assumption underlying statistical procedures. It is particularly helpful when sample sizes are small or when the distribution is suspected to be non-normal.
