Thermodynamics: An Engineering Approach Solution Manual 7th Edition

Q1: What is the Second Law of Thermodynamics?

A: The Second Law of Thermodynamics states that the total entropy of an isolated system always increases over time. This principle is used to analyze the efficiency of heat engines and other thermodynamic systems.

Q2: How do you calculate the change in entropy for a reversible process?

A: For a reversible process, the change in entropy is given by the integral of dQ/T over the path of the process. This integral represents the heat transferred reversibly from higher temperature to lower temperature, divided by the absolute temperature.

Q3: What is the enthalpy of formation?

A: The enthalpy of formation is the change in enthalpy when one mole of a compound is formed from its constituent elements in their standard states. This value is used to calculate the enthalpy of reactions involving the formation or decomposition of compounds.

Q4: How do you determine the equilibrium constant for a chemical reaction?

A: The equilibrium constant for a chemical reaction is calculated using the Gibbs free energy change. The Gibbs free energy change is related to the equilibrium constant through the equation: $\Delta G^\circ = -RT \ln K$, where ΔG° is the standard Gibbs free energy change, R is the gas constant, T is the temperature, and K is the equilibrium constant.

Q5: What is the efficiency of a heat engine?

A: The efficiency of a heat engine is defined as the ratio of the work done by the engine to the heat absorbed from the high-temperature reservoir. The maximum possible efficiency is given by the Carnot efficiency, which is determined by the temperatures of the high- and low-temperature reservoirs.
