### **1. Define electrical current.**

Answer: Electrical current is the flow of electric charge through a conductor. It is measured in amperes (A).

### **2. Explain the difference between series and parallel circuits.**

Answer: In a series circuit, the components are connected one after the other, so the current flows through each component in turn. In a parallel circuit, the components are connected in parallel, so the current has multiple paths to flow through.

### **3. What is Ohm's law?**

Answer: Ohm's law states that the voltage across a conductor is directly proportional to the current flowing through it and inversely proportional to its resistance. The equation for Ohm's law is  $V = IR$ , where  $V$  is voltage,  $I$  is current, and  $R$  is resistance.

### **4. Describe the function of a capacitor.**

Answer: A capacitor is a device that stores electrical charge. It consists of two metal plates separated by an insulating material. When a voltage is applied across the plates, it charges up by storing energy in the electric field between them. Capacitors are used to smooth out voltage fluctuations and store energy for later use.

### **5. What is the power factor of an AC circuit?**

Answer: The power factor of an AC circuit is the ratio of the real power to the apparent power. Real power is the power that is actually used to do work, while apparent power is the total power consumed by the circuit. The power factor is a dimensionless quantity that ranges from 0 to 1. A power factor of 1 indicates that all of the power consumed by the circuit is real power, while a power factor of 0 indicates that none of the power is real power.
