Transaction Processing Concepts and Techniques (The Morgan Kaufmann Series in Data Management Systems)

Q: What is a transaction in database systems?

A: A transaction is a logical unit of work that consists of a series of database operations that must be executed as an indivisible unit. All operations within a transaction either succeed or fail together, ensuring data integrity and consistency.

Q: Define the ACID properties of transactions.

A: ACID stands for Atomicity, Consistency, Isolation, and Durability. These properties guarantee that transactions are indivisible (atomic), maintain data integrity (consistent), execute independently of each other (isolated), and persist their effects despite system failures (durable).

Q: What is the importance of concurrency control in transaction processing?

A: Concurrency control prevents multiple transactions from modifying the same data simultaneously, which could lead to data inconsistencies. It ensures that data is always processed in a consistent manner, even when multiple users are accessing the database concurrently.

Q: Explain the concept of locking in transaction processing.

A: Locking is a concurrency control technique that prevents multiple transactions from modifying the same data concurrently. Locks are acquired on data items to restrict access to them during a transaction, ensuring that other transactions cannot modify the data until the locks are released.

Q: Discuss the trade-offs between optimistic and pessimistic concurrency control.

A: Optimistic concurrency control assumes that transactions are unlikely to conflict, and only checks for conflicts at the time of commit. Pessimistic concurrency control assumes that conflicts are likely, and acquires locks on data items immediately to prevent potential conflicts. Optimistic concurrency control is more efficient for low-conflict scenarios, while pessimistic concurrency control is more suitable for high-conflict scenarios.
