Question: Describe the three mechanisms of mass transfer and provide examples of each.

Answer: Mass transfer occurs through diffusion, convection, or migration. Diffusion is the movement of molecules from high concentration to low concentration, driven by a concentration gradient. Convection is the transfer of mass due to the movement of a fluid. Migration is the movement of ions due to an electrical potential gradient.

Question: Explain the concept of equilibrium in separation processes.

Answer: Equilibrium is a state where the driving force for separation is zero. In distillation, for example, equilibrium is reached when the vapor composition is equal to the liquid composition. In extraction, equilibrium is reached when the solute concentration is equal in both phases.

Question: Discuss the factors that affect the efficiency of a distillation process.

Answer: The efficiency of a distillation process is influenced by factors such as the number of trays, reflux ratio, and vapor-liquid equilibrium. Increasing the number of trays or reflux ratio improves the separation, while non-idealities in vapor-liquid equilibrium can reduce efficiency.

Question: Describe the principle of membrane separation processes and its applications.

Answer: Membrane separation processes utilize semipermeable membranes to selectively separate components based on size, charge, or polarity. Applications include desalination, water treatment, and biopharmaceutical production.

Question: Explain the concept of rate processes and how they relate to transport processes.

Answer: Rate processes describe the rate of change of a system over time. Transport processes are a specific type of rate process that involves the movement of matter or energy. Understanding the rates of transport processes is crucial for predicting and optimizing chemical processes.
