### **Understanding Exposure: A Q&A**

#### **What is exposure?**

Exposure in photography refers to the amount of light that reaches the camera's sensor. It's determined by three main factors: aperture, shutter speed, and ISO.

#### **How does aperture affect exposure?**

Aperture is the opening of the lens that controls the amount of light entering the camera. A wider aperture (lower f-number) allows more light in, resulting in a brighter image. Conversely, a narrower aperture (higher f-number) lets in less light, resulting in a darker image.

#### **How does shutter speed affect exposure?**

Shutter speed determines the duration of time that the shutter is open. A faster shutter speed (shorter duration) allows less light in, resulting in a brighter image. This is useful for freezing motion. A slower shutter speed (longer duration) allows

more light in, resulting in a darker image. This can be used to create motion blur.

### How does ISO affect exposure?

ISO is the sensitivity of the camera's sensor to light. A higher ISO rating makes the sensor more sensitive, allowing for brighter images in low-light conditions. However, it can also introduce noise into the image.

### How do I use these factors to control exposure?

To achieve the correct exposure, it's important to balance the three exposure factors. In general, a combination of a wider aperture, faster shutter speed, and lower ISO will result in a brighter image. Conversely, a combination of a narrower aperture, slower shutter speed, and higher ISO will result in a darker image.
