Word2Vec Word Embedding Tutorial in Python and TensorFlow

Q: What is word embedding? A: Word embedding is a technique that represents words as numerical vectors. These vectors capture the semantic and syntactic relationships between words, allowing them to be processed by machine learning algorithms.

Q: What is Word2Vec? A: Word2Vec is a popular word embedding method developed by Google. It uses a neural network to predict the context of a given word, based on the surrounding words in a text corpus. This prediction process helps determine the vector representation for each word.

Q: How to create word embeddings using Word2Vec in Python? A: Using the Gensim library in Python, we can create Word2Vec embeddings from a text corpus. The `Word2Vec` class allows us to train a model on text data, and then access the resulting word vectors.

```
import gensim
model = gensim.models.Word2Vec([["the", "quick", "brown", "fox"], ["jumpe
word_vectors = model.wv
```

Q: How to integrate Word2Vec embeddings into a TensorFlow model? A: TensorFlow provides the `tf.nn.embedding_lookup` function, which retrieves the word vectors for a list of input words. We can use this function to incorporate pre-

trained Word2Vec embeddings into a TensorFlow model.

```
import tensorflow as tf
words = ["the", "quick", "brown", "fox"]
embedding_matrix = tf.nn.embedding_lookup(word_vectors, words)
```

Q: What are the applications of word embeddings? A: Word embeddings are widely used in natural language processing tasks, including:

- Text classification

- Machine translation

- Named entity recognition

- Document summarization
